

### Overview

Kernel **supervised learning** for **sequence** objects  $\min_{f \in \mathcal{H}} \frac{1}{n} \sum_{i=1}^{n} L(y_i, f(\mathbf{x}_i)) + \frac{\mu}{2} \|f\|_{\mathcal{H}}^2$ 

•  $\mathbf{x}_1, \ldots \mathbf{x}_n \in \mathcal{X}$  are sequences (biological sequences or texts).

**Goal**: learning a **predictive** and **interpretable** function  $f : \mathcal{X} \to \mathcal{Y}$ .

### From k-mers to gap-allowed k-mers modeling

Convolutional kernel networks [1] that model k-mers:

 $K_{\mathsf{CKN}}(\mathbf{x}, \mathbf{x}') = \sum_{i=1}^{|\mathbf{x}|} \sum_{j=1}^{|\mathbf{x}'|} K_0\left(\mathbf{x}[i:i+k], \mathbf{x}'[j:j+k]\right)$ 

- $K_0$  is a Gaussian kernel over **one-hot** representations of k-mers.
- A continuous relaxation of the mismatch kernel.
- $\varphi(\mathbf{x}) := \sum_{j=1}^{|\mathbf{x}|} \varphi_0(\mathbf{x}[j:j+k])$  with  $\varphi_0$  the kernel mapping associated to  $K_0$ .
- Scalable and task-adaptive with Nyström approximation. Interpretable using end-to-end training with few filters.
- Limitation: unable to capture gapped motifs.

### Recurrent kernel networks that generalize k-mers with gaps:

$$\mathcal{L}_{\mathsf{RKN}}(\mathbf{x}, \mathbf{x}') = \sum_{\mathbf{i} \in \mathcal{I}(k, |\mathbf{x}|)} \sum_{\mathbf{j} \in \mathcal{I}(k, |\mathbf{x}'|)} \lambda^{\mathsf{gaps}(\mathbf{i})} \lambda^{\mathsf{gaps}(\mathbf{j})} K_0(\mathbf{x}[\mathbf{i}], \mathbf{x}')$$

- Take gapped k-mers into account.  $\lambda^{gaps(i)}$  penalizes the gaps.
- $\varphi(\mathbf{x}) = \sum_{\mathbf{i} \in \mathcal{I}(k, |\mathbf{x}|)} \lambda^{\mathsf{gaps}(\mathbf{i})} \varphi_0(\mathbf{x}[\mathbf{i}]).$
- Computationally fast using dynamic programming.
- Leads to a particular RNN with a kernel interpretation.

# **Definition of gap-allowed k-mers**

- For  $1 \le k \le n \in \mathbb{N}$ , we denote by  $\mathcal{I}(k, n)$  the set of sequences of indices with k elements  $\mathbf{i} = (i_1, \ldots, i_k)$ , with  $1 \le i_1 < \cdots < i_k \le n$ .
- For a sequence  $\mathbf{x} = x_1 \dots x_n \in \mathcal{X}$  of length n, for a sequence of indices  $\mathbf{i} \in \mathcal{I}(k, n)$ , we define a k-substring as:

$$\mathbf{x}[\mathbf{i}] = x_{i_1} x_{i_2} \dots x_{i_k}$$

The length of the gaps in the substring is

 $gaps(\mathbf{i}) = number of gaps in the substring indices.$ 

• Example:  $\mathbf{x} = \mathsf{BAARACADACRB}$ 

$$i = (4, 5, 8, 9, 11)$$
  $x[i] = RADAR$  gaps(i)

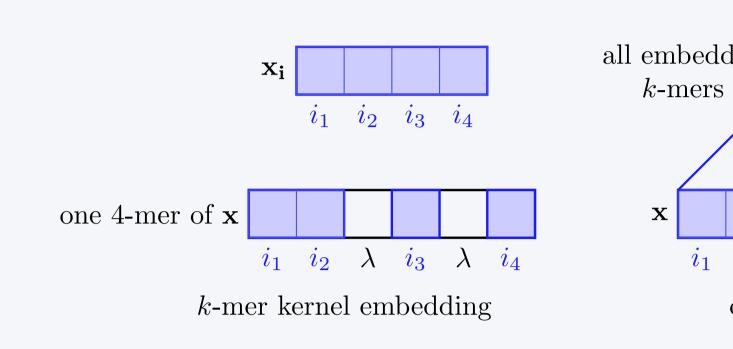

# **Recurrent Kernel Networks**

<sup>+</sup>CNRS - firstname.lastname@univ-lyon1.fr

## A feature map of RKN

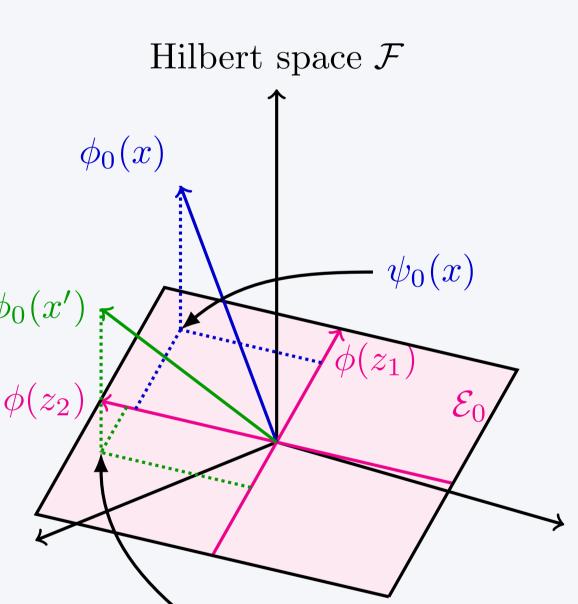

• A feature vector of RKN for x is a mixture of Gaussians centered at  $x[\mathbf{i}]$ , weighted by the corresponding  $\lambda^{gaps(\mathbf{i})}$ .  $\lambda^2 \varphi(\mathbf{x_i})$ 

# **Nyström approximation and RNNs**

### Nyström approximation:

$$\mathcal{E}_0 = \text{span}(\varphi_0(z_1), \dots, \varphi_0(z_q))$$
  
 $\psi_0(x) := K_{ZZ}^{-\frac{1}{2}} K_Z(x)$   
where  $[K_{ZZ}]_{ij} = K_0(z_i, z_j)$   
and  $[K_Z(x)]_i = K_0(z_i, x).$ 

Finite-dimensional projection of the kernel map: given a set of anchor points  $Z = (z_1, \ldots, z_q)$  with  $z_i \in \mathbb{R}^{k \times d}$ , we project  $\varphi_0(x)$ orthogonally onto  $\mathcal{E}_0$  such that  $K_0(x, x') \approx \langle \psi_0(x), \psi_0(x') \rangle_{\mathbb{R}^q}$ . An approximate feature map for  $K_{\rm RKN}$  is

$$\psi_k(\mathbf{x}) = \sum_{\mathbf{i}\in\mathcal{I}(k,|\mathbf{x}|)} \lambda^{\mathsf{gaps}(\mathbf{i})} \psi_0(\mathbf{x}[\mathbf{i}]) = K_{ZZ}^{-\frac{1}{2}} \sum_{\mathbf{i}\in\mathcal{I}} \mathbf{x}_{ZZ}^{-\frac{1}{2}} \sum_{\mathbf{i}\in\mathcal{I}} \mathbf{x}_{ZZ}^{-\frac{1$$

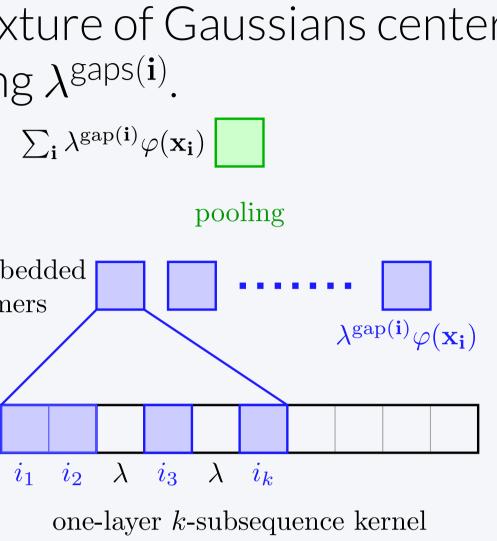

Fast computation with dynamic programming: For any  $j \in \{1, ..., k\}$  and  $t \in \{1, ..., |\mathbf{x}|\}$ ,  $\psi_j(\mathbf{x}_{1:t}) = K_{Z_jZ_j}^{-\frac{1}{2}} \mathbf{h}_j[t]$ where  $\mathbf{c}_{i}[t]$  and  $\mathbf{h}_{i}[t]$  in  $\mathbb{R}^{q}$  obeying the recursion  $\mathbf{c}_{i}[1] = \mathbf{h}_{i}[1] = 0$  $c_0[t] = 1$  $\mathbf{c}_{i}[t] = \lambda \mathbf{c}_{i}[t-1] + \mathbf{c}_{i-1}[t-1] \odot \kappa$  $\mathbf{h}_{i}[t] = \mathbf{h}_{i}[t-1] + \mathbf{c}_{i-1}[t-1] \odot \kappa(t)$ 

where  $\kappa$  is a non-linear function  $\kappa(x) = e^{i t}$  $\mathbb{R}^{qd}$  whose *i*-th row is the *j*-th row of  $z_i$ .

 $\mathbf{x}'[\mathbf{j}])$ 

= 3

# Dexiong Chen<sup>†</sup> Laurent Jacob<sup>‡</sup> Julien Mairal<sup>†</sup>

 $\lambda^{\operatorname{gaps}(\mathbf{i})} K_Z(\mathbf{x}[\mathbf{i}]) \in \mathbb{R}^q.$  $Z(k, |\mathbf{x}|)$ 

$$1 \leq j \leq k,$$
  

$$1 \leq t \leq |\mathbf{x}|,$$
  

$$z(Z_j \mathbf{x}_t) \quad 1 \leq j \leq k,$$
  

$$Z_j \mathbf{x}_t) \quad 1 \leq j \leq k,$$
  

$$1 \leq j \leq k,$$
  

$$z^{\alpha(x-1)} \text{ and } Z_j \text{ is a matrix in}$$

The supervised learning problem becomes

$$\min_{\mathbf{w}\in\mathbb{R}^q}\frac{1}{n}\sum_{i=1}^n L$$

where  $\psi_k$  depends on Z. The model can be trained in 2 ways:

- Supervised: jointly learning Z and w with SGD.

### Learning strategies

# $L\left(\langle \psi_k(\mathbf{x}_i), \mathbf{w} \rangle, y_i\right) + \frac{\mu}{2} \|\mathbf{w}\|^2,$

• **Unsupervised:** learning *Z* with **K-means** over (subsampled) k-mers (eventually with gaps). Then train a linear classifier.

• The **sum** can be replaced by a **max**, the corresponding recursive equations can be obtained by replacing all the sum with max. • Generalized max pooling (GMP): build a representation  $\varphi_{gmp}$ such that  $\langle \varphi_{gmp}, \varphi_i \rangle_{\mathcal{H}} = 1$  for a set of features  $(\varphi_1, \ldots, \varphi_N)$  in  $\mathcal{H}^N$ . Multilayer extension and link with string kernels in [1].
